Abstract

After former Houston Astros pitcher, Mike Fiers, accused the Astros of cheating by setting up cameras in center field to steal signs, it became necessary to find evidence to determine if these claims were true. Our group tried to find statistical evidence to support Fiers' claims. Because the Astros could only cheat at home, we tried to find any statistically significant difference between the Astros batting performance when at home and when on the road. We used box plots to compare some basic batting stats for the Astros when they are at home vs. away. We ran a monte carlo simulation to check if the observed difference between home and away runs indicated statistical significance. We ran a t-test to determine if the statistical difference in runs scored came from the advantage provided from the Astros home park. We found that the Astros team batting average was significantly better at home than away. We ran another t-test to compare the Astros to the rest of the league. We found that there is no distinction between the Astros home statistics and the other teams' home statistics. We then used an additional dataset that gave us Outside swing% and Inside Swing% which allowed us to determine if the players knew what pitch was coming, would they swing or not swing. We found percentage changes In-Zone% and Out-Zone%. Both the in-zone% increase and the out-zone% decrease, so that adds some evidence to the Astros improvement in 2017 (perhaps caused by cheating).

Description of Data

Baseball is an American sport played between two teams. One team plays defense and has a player (pitcher) try to throw the ball past the other team's batter who tries to hit the ball. If the batting team successfully hits the ball enough times they can score runs (points). We will use data sets from baseball-reference.com which contain team and individual statistics. This database also offers data 'splits', which show comparisons between home and away games. For our primary analysis, we will be focusing on the Houston Astros 2017 Team Batting Splits and the 2017 Individual Player Batting Splits. These data sets outline various different statistics of the Houston Astros 2017 season in which it was confirmed that they had cheated in home games. We will use the 'splits' data sets to determine a difference of statistics between home and away games. This database also contains data on the Astros for different seasons and different teams. Depending on the results of our initial analysis, we will compare the players on the roster of the 2017 Astros to previous seasons to determine a difference in performance before and after cheating. Our statistical question is whether or not

the 2017 Houston Astros cheated. Two years after the alleged cheating occurred, reports from a player who was on the 2017 Astros alleged that there were cameras positioned in the Astros home field stadium, Minute Maid Park in Houston, that could see the relayed signs between the pitcher and catcher. Note: the catcher communicates to the pitcher what pitch the pitcher should throw based on a series of hand movements in between pitches. The Houston Astros camera could see these hand signals and people were in charge of watching the film and decoding the symbols to determine what pitch was coming. Once a pitch was shown, members of the Astros would relay what pitch was coming to the batter through their own series of symbols (most infamously a banging of a garbage can).

The Astros only had this technology at their Home Stadium, so they should have higher performance at home compared to on the road. Note: this sign decoding should reason that only their batting improved at home and not their pitching. We used several stats for measuring their performance.

Statistical Questions

- Is there a noticeable difference between the batting splits for home and away games of the Houston Astros team during the 2017 season?
- How does this difference, if any, compare to other teams' performance in the MLB during the 2017 season?
- Is there sufficient statistical evidence to suggest the Houston Astros benefited from cheating in the 2017 season?
 - If there is, how much may the cheating have affected their season? And what would their season have looked like if they didn't cheat?

Why We Chose This Dataset

- This has been a controversy within the baseball community regarded to be one of the biggest cheating scandals in the sport's history.
- In 2017 the Houston Astros won the world series. However, it came out in November of 2019 that they were using technology to steal signs during home games.
- To us, this data set is interesting because it contains (in detail) records of each game, each player, and almost all variables that could take place in this event. So, this dataset is very in depth and useful for testing hypotheses thoroughly regarding the incident. Like they said "Numbers don't lie"!

Variables

Below is a list of some important variables in our dataset:

Name	Abbr.	Description
On base and slugging percentage	OPS	Measures a players On base Percentage (percentage of At bats a player has gotten on base) and a players slugging percentage (a weighted batting average)
On base and slugging percentage (Player)	tOPS	This is adjusted so that 100 is the team average, so if tOPS is less than 100, the batters did worse, and if it is higher than 100, the batters did better.
On base and slugging percentage (Team and Player)	sOPS	This is adjusted so that 100 is the league average, so if sOPS is less than 100, the batters did worse than the league average and if it is higher than 100, the batters did better.
Runs Batted In	RBI	The number of runs a player has created by hitting a player home. Weights a players higher
Hits	H	When a batter reaches base without doing so via error or fielder's choice.
Homeruns	HR	Scored when the ball is hit in such a way that the batter is able to circle the bases and reach home safely.

Name	Abbr.	Description
Walks	W	Occurs when a pitcher throws four pitches outside of the strike zone, none of which are swung at by the batter.
Batting Average	BA	Percentage of At Bats a player gets a hit.
In Zone Percent	IZP	The percent of pitches thrown in the strike zone that a player swings at.
Out Zone Percent	OZP	The percent of pitches thrown outside the strike zone that a player swings at.

Loading Data

```
# will store the data for all teams in the 2017 season
season_2017 <- NA
data_empty <- TRUE

# Getting initial path data
data_path <- "./data"
data_dirs <- list.files(data_path)
data_dirs <- data_dirs[!str_detect(data_dirs, ".csv")]

# iteratively get all csv file paths and store them
for(path in data_dirs){
  # gets the directory for a specific teams csv files
  team_dir <- paste(data_path, path, sep="/")
  csv_list <- list.files(team_dir)

  # steps through csv files, loads and edits them as dataframes
  for(csv in csv_list){
    # get full path, and other information from csv name
    full_path <- paste(team_dir, csv, sep="/")
    split <- ifelse(str_detect(csv, "home"), "HOME", "AWAY")
    team_name <- str_split_fixed(team_dir, pattern="data/", 2)[2]

    # Read in data
    df <- read.csv(full_path)%>%
      mutate(Name = str_split_fixed(Name, "\\\\", 2)[,1]) %>%
      mutate(split = split, team = team_name)
    df <- df[ -length(df[,1]), ]

    # binds all teams data together
    if(data_empty){
      season_2017 <- df
      data_empty <- FALSE
    }else {
      season_2017 <- rbind(season_2017, df, make.row.names=TRUE)
    }
  }
}

astros_2017 <- season_2017 %>%
  filter(team=="astros", AB != 0)
```

```

zones <- read.csv('./data/zone_swings.csv')
zones_clean <- zones %>%
  unite('Name', first_name:last_name, remove = TRUE) %>%
  mutate(Name = str_replace(Name, " ", "")) %>%
  mutate(Name = str_replace(Name, "_", " ")) %>%
  select(Name, out_zone_swing, in_zone_swing, year) %>%
  arrange(Name)

astros_z <- left_join(zones_clean, astros_2017, by = "Name") %>%
  select(Name, out_zone_swing, in_zone_swing, year, team) %>%
  drop_na() %>%
  unique()

not_astros_z <- left_join(zones_clean, not_astros, by = "Name") %>%

  drop_na() %>%
  unique()

all_zone_data <- rbind(astros_all_z, not_astros_all_z)

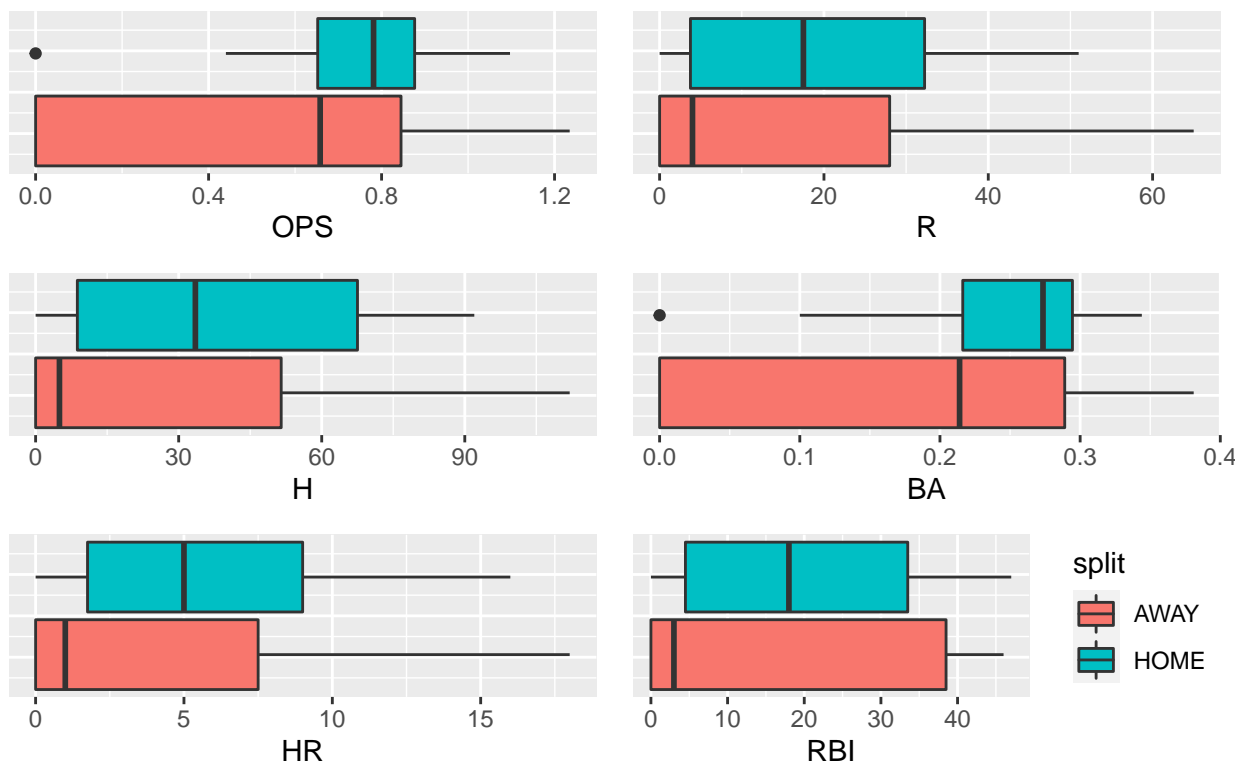

```

Preliminary Plots

Comparing The Astros 2017 Home and Away Data

to start we will look at some of the variables we take a look some comparisons of specific variables between home and away games.

Astros 2017 data – Home vs Away

These box plots show how there is a clear difference between home and away games. The largest difference is in average Hits (H) per season that a player gets between home and away games.

Runs analysis - Home vs. Away

To do this analysis, we will be doing a monte carlo simulation on the difference of average runs a player gets per season between home and away games. Runs will be modeled by a poisson random variable. Under the assumption that Runs from home and away games comes from the same distribution, we will set lambda as the mean of runs for home and away games combined.

After performing a 95% confidence interval on our data, we see that our observed difference falls outside of the confidence interval, leading us to reject our initial assumption. Thus, we can say with 95% confidence that there is statistical significance in the difference of Run means between home and away games.

However, because Away game Runs are lower than Home game Runs, this implies that the Astros cheating had a positive effect on their performance.

Is It Just a Home-Field Advantage

Since our original statistical question is basically “can we prove that the Astros cheated in the 2017 season?” we want to determine if the results we found in the confidence interval above just prove that a home field advantage exists or if the Astros have a better home field advantage due to the existence of cheating.

To do this we will perform some two sample t tests to determine a difference between the average statistics between Astros at home and other teams at their home stadium. We have realized that sign stealing should have a higher effect on players batting averages because it allowed the astros players to know which kind of pitch was coming in and thus have a better chance at hitting the ball. Batting Average is calculated as $BA = Hits/AtBats$.

```
##
## Welch Two Sample t-test
```

```
##
## data:  astros_home$BA and astros_away$BA
## t = 2.2676, df = 48.977, p-value = 0.0278
## alternative hypothesis: true difference in means is not equal to 0
## 95 percent confidence interval:
##  0.007848595 0.130125598
## sample estimates:
## mean of x mean of y
## 0.2466000 0.1776129
```

Above we see that the batting average of the Astros is significantly better at home than away. This again does not show conclusive evidence that they cheated, but instead adds strength to our earlier analysis that the Astros definitely have some sort of a home field advantage. Next we will compare the Astros with the rest of the league, by performing another two sample t test between the astros home games and the home games of all other teams in the league.

```
##
## Welch Two Sample t-test
##
## data:  astros_home$BA and not_astros_home$BA
## t = 1.6987, df = 21.411, p-value = 0.1039
## alternative hypothesis: true difference in means is not equal to 0
## 95 percent confidence interval:
## -0.007287044 0.072700567
## sample estimates:
## mean of x mean of y
## 0.2466000 0.2138932
```

Here the results do not lead us anywhere conclusive as our p-value is too high to reject the hypothesis that the true mean of the distribution of the Astros batting average is the same as the true mean of the batting average of all other teams. We have also tried this in other variables in our data set as well, however the results have all been similar. There is no distinction between the astros home statistics versus other teams home statistics.

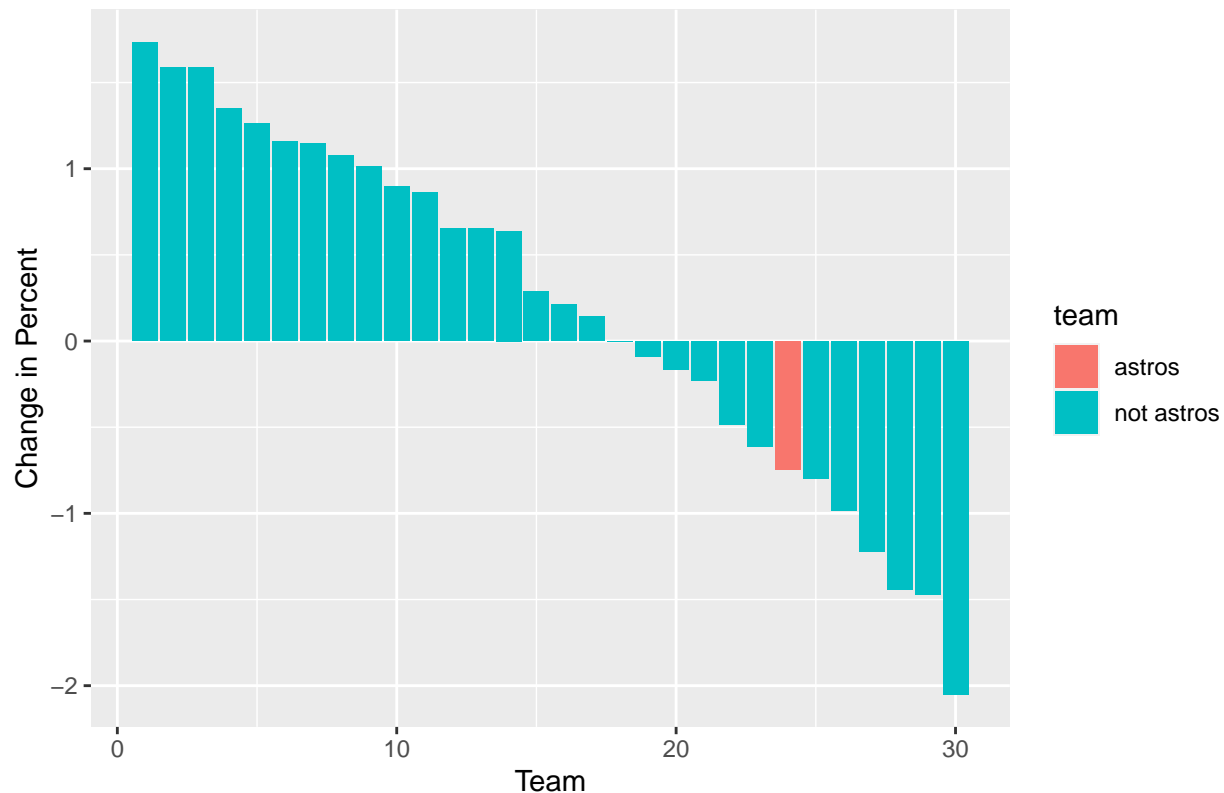

A New Approach

So far it seems that our data is too general for our statistical question. There are a myriad of different factors that play into how a team does in a season, differing game to game. We believe that to tackle this question we need to take a look at more in-depth statistics than just player hits, batting average, etc. We have found a new dataset from “Baseball Savant” that offer’s player data for the percent of pitches that are out of the strike zone that a player swings at and the percent of pitches that are in the strike zone that a player swings at.

Change in In-zone Percent Between 2016 and 2017

Change in Out-zone Percent Between 2016 and 2017

These two graphs show the change in Out-zone percent and In-zone percent between 2016 and 2017 for each team. We highlighted the Astros in red to distinguish them from the rest of the teams. A positive increase in In-zone percentage means that a team is swinging at more pitches that are thrown in the strike zone. A positive increase in Out-zone percentage means that a team is swinging at more pitches that are thrown outside the strike zone than the year previous. For a team to have improved from the year before they will want to increase their in-zone percent and decrease their out-zone percent. Here we can see that the Astros have done this, however it doesn't look like they have improved a significant amount compared to other teams as their change for both in-zone and out-zone is within 1 percent.

Discussion on Progress/Challenges

Challenges:

- On our last project report, the results that we gathered from the data were not what we expected. We originally cleaned the dataset wrong and it affected the outcome, giving us reason to believe the Astros didn't cheat. After going back and changing how we read in the data, our graphs prove what we were originally expecting, and show initial evidence that they were cheating. Our original findings were very surprising because this cheating scandal wouldn't have been a scandal if it weren't for some correlation and evidence that suggest they did. This was a big challenge because after our last project report, we thought we were gonna have to go back and change our whole project. But now we are back on track and can continue the analysis of our questions.
- Another challenge we faced during this project report was trying to figure out how to use a linear model in our analysis. We originally wanted to use a regression model on all of the variables in our dataset to predict wins and then we could see if home games (the supposed cheating) was a statistically significant variable. After initially trying this, we realized this approach was not a very good/strong

indication of how home games helped them cheat. Then, we thought it would be beneficial to compare individual Astro players pre-season stats, to that of the regular season, and compare home and away. This also came with its issues though because there wasn't individual player data for preseason. So we moved onto our next thought process

- From the data site Kieth gave us from the last project report, we found a perfect data set split up into the home and away games, but there were no column names for 161 variables. So we used python to assign column names from the reference sheet online.
- In doing this, we found out how hard it is to try and piece together all the datasets. This method also increases the margin of error, which is something we can compute and analyze for the final report.
- After discussing our project in office hours and realizing regression would not really prove anything, we decided to just keep going down the same path of comparing home and away splits. This led us to multiple 2 samples t-tests between the 3 significant stats (RBI,HR,and BA) when the astros is at home versus when they are away, and when the astros is at home versus when the others is at home to see if there are any notable or substantial differences. Our assumption is that if the differences between the astros stats at home and when they are away is substantial, then they play better due to home court advantage. But if the difference is notable, there might be more going on and we are in the right track. To "level" the playing field and strenthen our analysis that the astros was not just too "good" that season, we also did test for when the astros is at home versus when other teams (as a whole) is at home to see if the differences could help us conculde or strengthen our assumption. The challenge with this was that no matter how we computed home and away splits (we tried many different ways), there was nothing really jumping out at us. We attempted bootstrap but the results again were no good.
- This led to see that our data just wasn't specific enough. We couldn't find any real evidence that the Astros had a advantage at home do to cheating. If we want to see if the actual act of sign stealing had an impact on the success of the Astros at home, and not just do to home field advantage, we had to find more specific data. Although we were told we shouldn't be gathering any more data, we thought if we wanted be able to answer our statistical questions in any way, we would need to gather more data on in (strike) zone swing percentage and out of (strike) zone percentage. This way, we can actually see if the batter having the knowledge to what pitch he was gonna be thrown actually impacted his hits at home in comparison to away.
- If we had more time, we would spend much more time searching for a data set with in zone and out zone swing percentage for home and away. The only easily available data set to grab without too many cleaning issues combined home and away zone swing percentages, making it impossible for us to fully answer our question. We were able, however, to see a significant difference in the zones swing percentage from the previous year, (2016) to the cheating year, showing us that there is definitely more to be explored on this path.

Progress:

- We came to the realization that some of our data cleaning from our last project report was skewing the results. We fixed that problem, re-fit the previous graphs, and re-analyzed them
- We spend a tremendous amount of time reading in new data and cleaning it, in order to form a regression model. After forming a linear model to predict win_percentage based on Runs, Hits, Runs Batted In, Home Runs, and Split (Home vs, Away), we found that the model sucks, like a lot. So we will need to adapt our model to work better in the future, but we did not have enough time to finish it now.
- In experimenting with different ways to analyze home and away splits, we found that creating our own batting average would be best because we could create one for each home and away game according to the player. In doing this we also realized that teams rosters are different for home and away and this,

along with players who never got up to the plate once in a whole season were skewing our results. In an attempt to resolve this, we only analyzed players who got up to bat once per game, or 162 times for all the regular season games in the pre-covid 2017 season.

Conclusion

We have tried a lot of different things, however most of them do not lead us anywhere significant in trying to answer if the 2017 Houston Astros cheated or not. We have shown that the Astros do have a home field advantage, however the sort of home field advantage that they have does not seem out of the ordinary when compared to other teams. We have also seen that their batting seems to have improved between the 2016 and 2017 season, but they again do not seem to have improved drastically in comparison to the other teams. Overall, there are hundreds of variables that play into how a team does in a season. Perhaps, the Houston Astros truly improved and should've won during the 2017 season even without cheating, or maybe their cheating helped boost their confidence. But the data that we would need to prove this is hard to obtain and is most likely only able to be obtained by the major league teams statistician. Although we weren't able to come to a conclusive result, we were able to see there is some aspect that goes into having a home field advantage, but its very hard to single out just one variable.

Some potential questions that we would want to further look into is what statistical advantage did the Astros actually gained from stealing the signs of the other teams throughout the season. Instead of looking at overall games, we could at specific aspects of the game that was improved upon by each player in the home games.
